

ABSTRACT

A gaming terminal for conducting a wagering game includes a wager-input device and a button panel located below the wager-input device. The button panel includes a plurality of mechanical buttons for receiving inputs from a player. The gaming terminal further includes a main display for displaying a randomly selected outcome from a plurality of outcomes and a secondary display for displaying information about the wager inputs received from the wager-input device and, during the wagering game, for displaying game-play information related to the plurality of outcomes. The secondary display is located between the button panel and the main display, contiguous with the button panel, and to the side of the wager-input device. The secondary display acts in unison with the main display to illustrate continuous movement of images related to the randomly selected outcome, the images moving between the main display and the secondary display.
